

STAR FORMATION IN A TURBULENT MOLECULAR CLOUD SELF-REGULATED BY PHOTO-IONISATION FEEDBACK

A NUMERICAL EXPERIMENT

gavagnin@physik.uzh.ch

Stars form in molecular clouds. How do we get to gas-free (bound? unbound?) star clusters?
We study the effect of massive stars feedback on SC properties.

INTRO

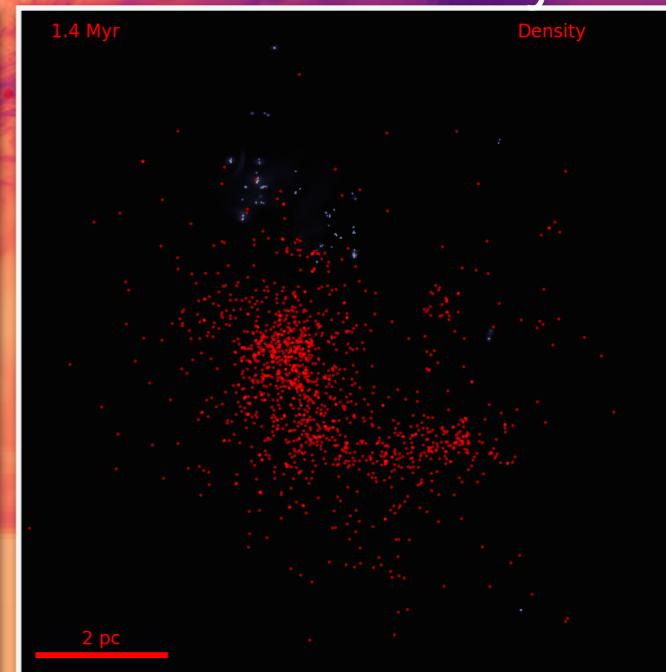

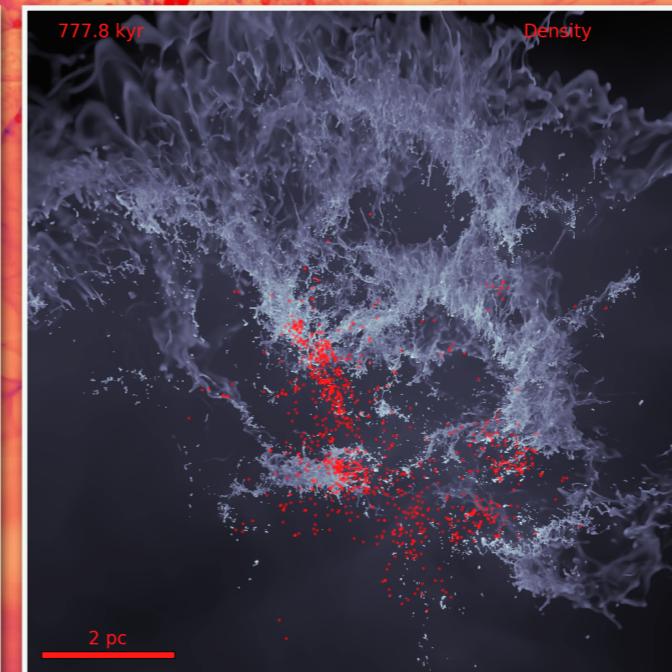

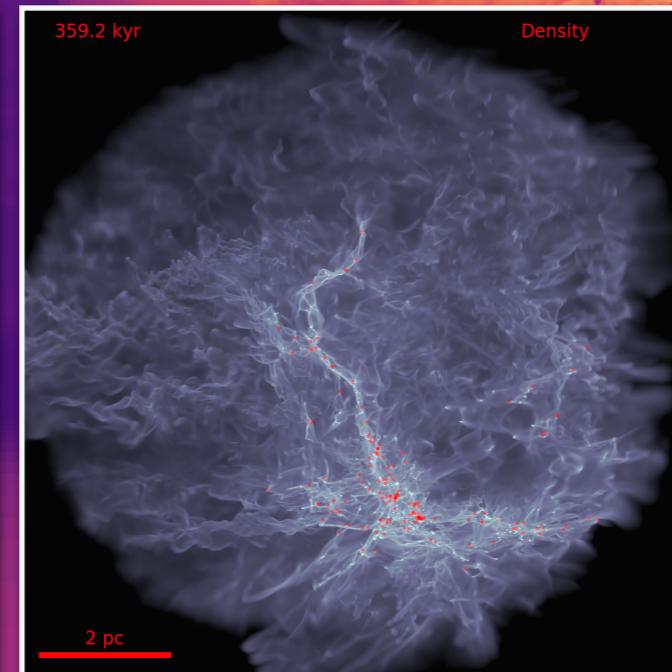

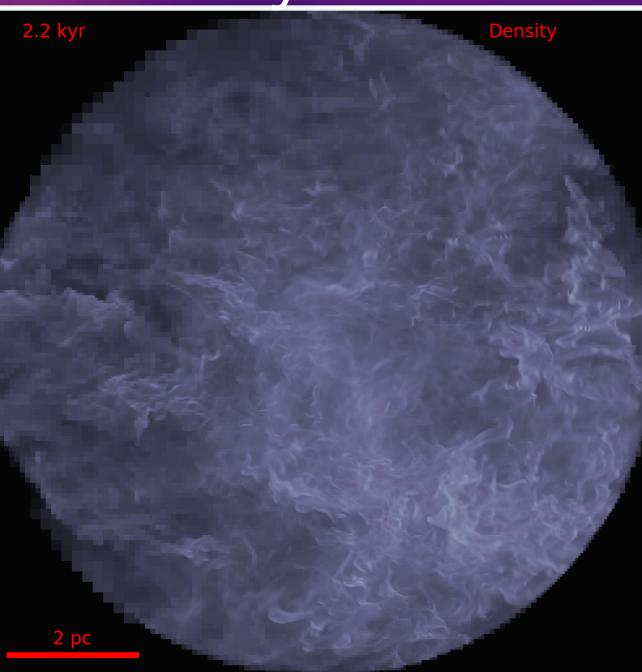

NUMERICAL METHODS

RAMSES (Teyssier02) + RHD (Rosdahl+13) =
(Magneto-)hydrodynamics solver with self-gravity on adaptive mesh+
propagation of photons and interaction with gas via photoionisation

SIMULATION SETUP

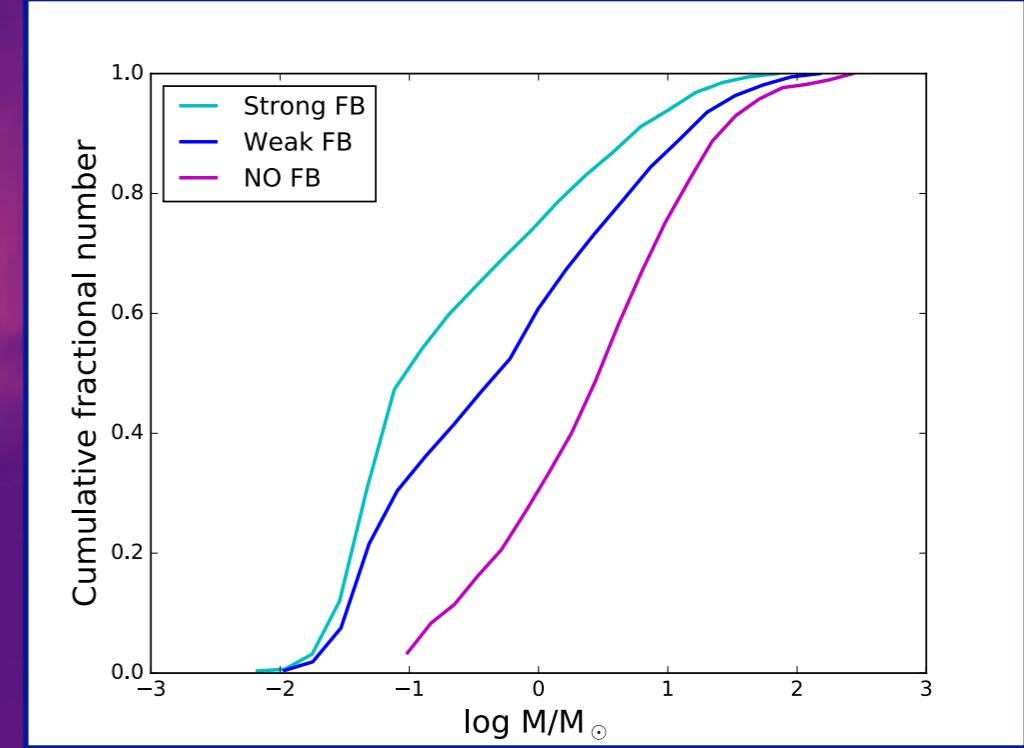

- Radiative hydrodynamic simulations of turbulent molecular cloud
- Mass $2.5 \times 10^4 M_{\text{SUN}}$, Radius 5 pc
- Sink particles implementation (Bleuler+15)
- UV feedback is modelled coupling every sink with a self-consistent photo-ionising luminosity function. 3 regimes: STRONG, WEAK, NO FB

0 Myr

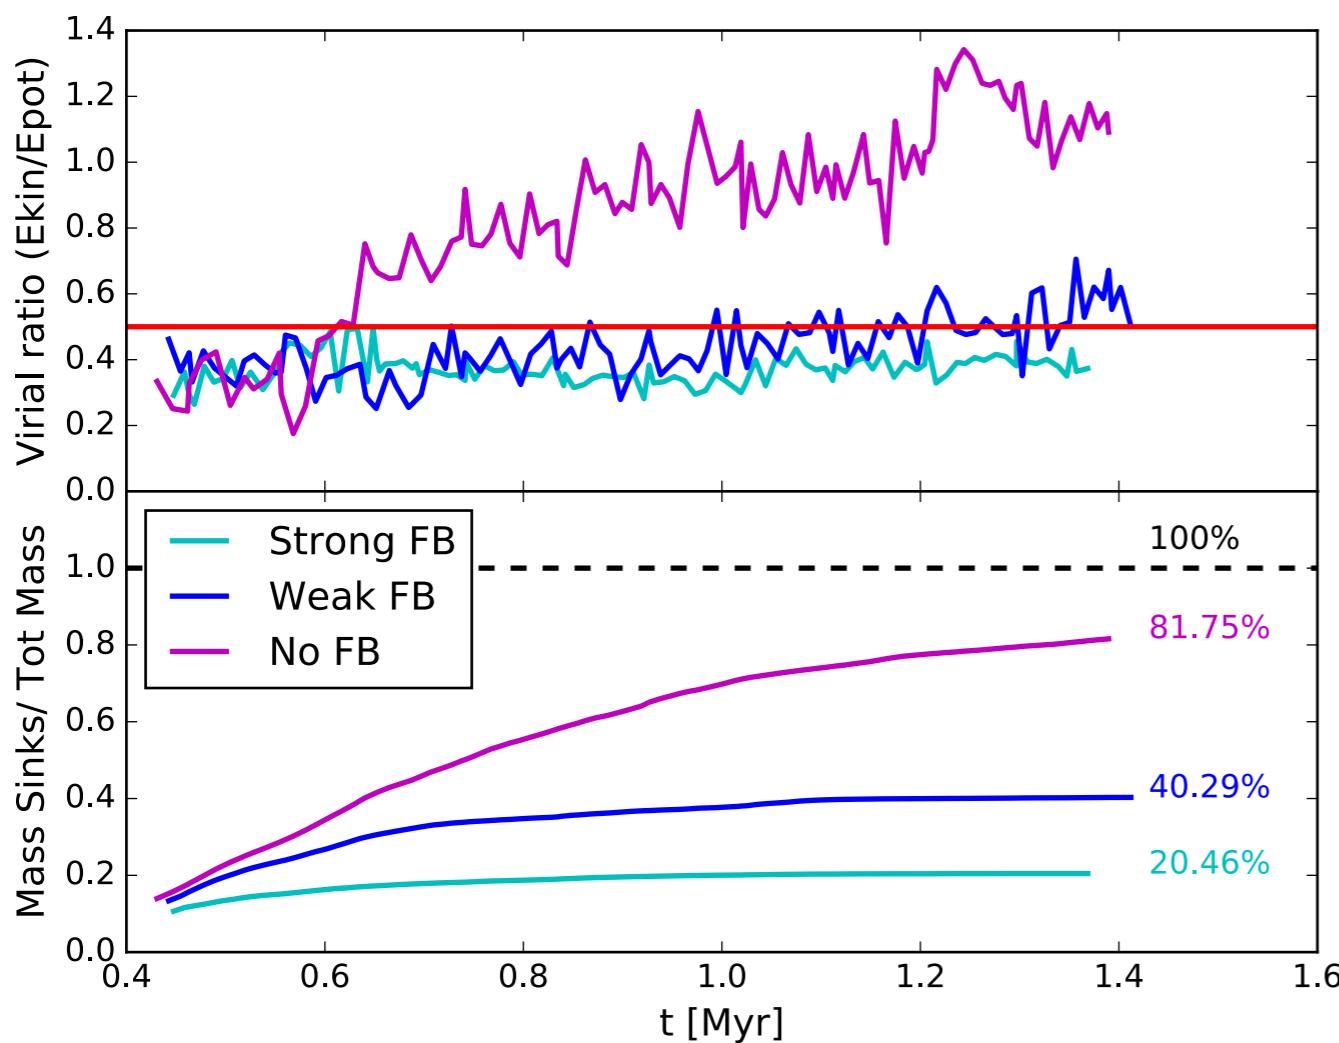

1.5 Myr

	STRONG	WEAK	NO FB
N SINKS	1425	1118	1153
MAX MASS [M _{SUN}]	115	247	410

Virial parameter & SFE

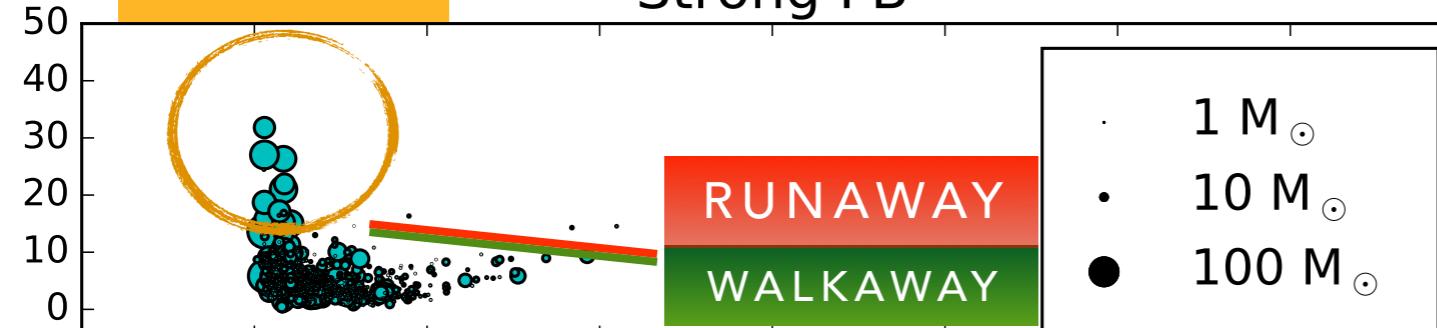

Gas not-expelled (<5pc)

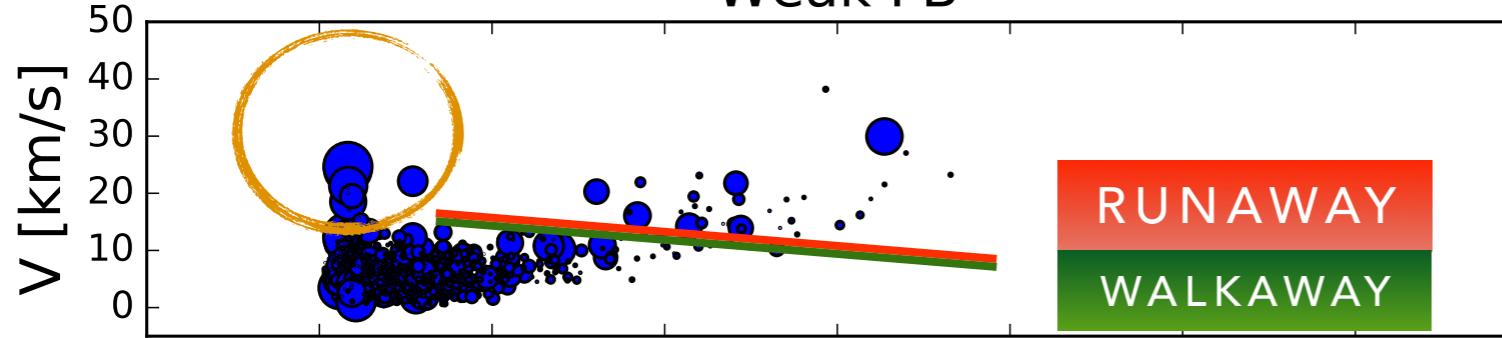

BINARIES

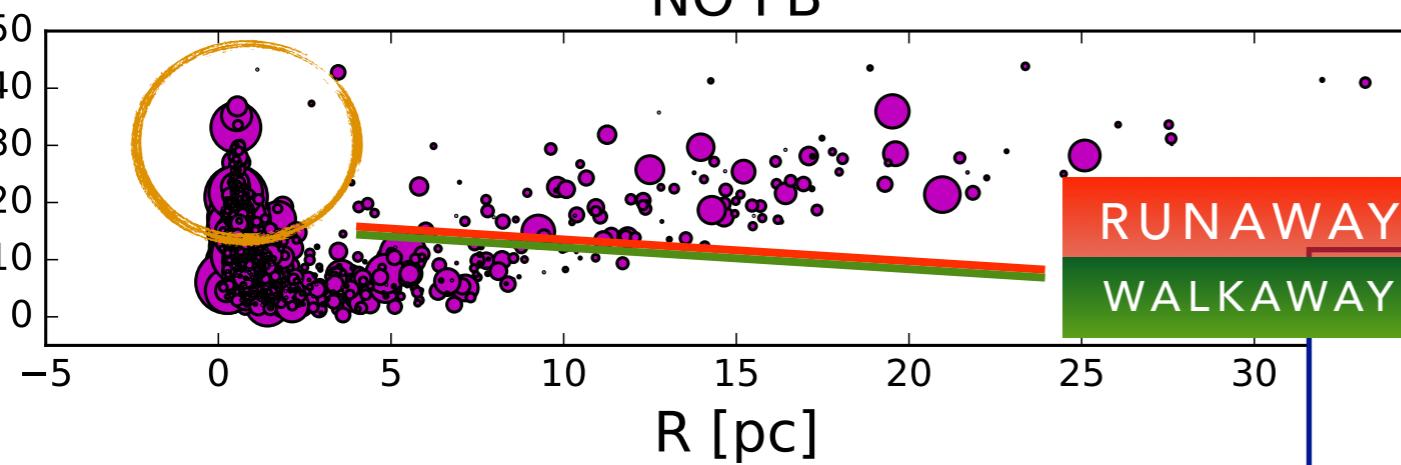

Strong FB

Weak FB

NO FB

Escapers

RUNAWAY stars: fast ejections within binary/multiple systems

WALKAWAY stars: slow ejections from relaxation interactions

Mass segregation

STRONG FB consistent with observations of mass segregation in YSCs (e.g. NGC 3603)
